2 GEOPHYSICAL INSTITUTE
| UNIVERSITY OF ALASKA

COLLEGE, ALASKA

"High Latitude Geophysical Data" is published by the Institute with the objective of presenting current geophysical data related to polar ionospheric activity. Because of the research nature of the Institute's program, the type of material presented and the experimental and scaling methods may be novel and are subject to change. Thus the methods are described in sufficient detail to assure correct interpretation of data.

V. P. Hessler, Editor

30 MC/S COSMIC NOISE LEVEL

R. Parthasarathy
Assoc. Professor of Physics

and

J. L. Hook
Assistant Geophysicist

This section consists of reproductions of the cosmic radio noise level at 30 Mc/s, monitored at College, Alaska (64.65°N , 256.56°E , geomagnetic).

The zenith directed antenna is a pair of crossed, 3-element Yagis, responding to the noise in the right circular mode. The beam has approximate rotational symmetry, with about 60 degrees between half-power points. The power linear receiver system is calibrated at 1.0, 2.0, 3.0, 4.0 and 5.0 milliamp of the diode plate current.

The variation of the noise level at College is primarily due to the variation of the precipitating auroral particles. It is known that the energies of these primary particles (electrons and protons) that are of immediate relevance to the luminosity of the auroral displays are about a few kilovolts, and that the integral energy spectrum of the flux expressed as a power law of the energy is characterized by an exponent, minus γ , the γ varying from about two to five. It is also known from observations at 37 Mc/s with antenna beams comparable to the angular dimensions of the displays (i.e., a few degrees in the meridian plane) that, in general, the radiowave absorption in any direction is only poorly specified by the luminosity of the display. The radiowave absorption at a single frequency is not capable of specifying the height distribution of ionization responsible for the absorption, and hence the energies of the primary particles. Simultaneous absorption data in a number of frequencies in the HF and VHF band have, therefore, been utilized in the past for deriving the ionization profile as a function of height over College. The derived profiles suggest that the VHF absorption is dominantly controlled by the high energy tail ($20 \text{ kev} < E < 100 \text{ kev}$) of the precipitating electrons.

The recording and reproduction of these traces is financially supported by the National Aeronautics and Space Administration under Contract NAS5-3595.

TELLURIC CURRENT ACTIVITY

V. P. Hessler
Professor of Geophysics

The electrode field is located south of the Geophysical Institute Ballaine Lake Field site ($64^{\circ}51'N$ and $147^{\circ}50'W$ geographic and $64^{\circ}37'N$ and $256^{\circ}30'E$ geomagnetic). The 200 meter spaced electrodes are aligned in the N-S geographic meridian.

N-S telluric current records. These records are made on an L&N Speedomax recorder, with a 5 second full scale response rate, at 3 in/hr and at 1000 mv/km full scale range. Since the telluric perturbation vector tends to be linearly polarized (N $35^{\circ}W$ geographic at this site) the N-S trace alone gives a good indication of the total activity. These telluric records always carry much more fine structure than the corresponding magnetograms and thus are a more sensitive indicator of ionospheric activity.

N-S telluric amplitude activity. The N-S telluric trace is scaled for hourly values of arithmetic range in a manner similar to that used in scaling magnetic K-indices. By range is meant the difference between the greatest positive and negative departure from an arbitrarily assigned zero trace (the diurnal variation at College is negligible in comparison with the disturbance phenomena). Monthly correlation coefficients between magnetic A figures and telluric amplitude scalings are always close to 0.95. Thus the telluric amplitude activity scalings presented herein are an index of ionospheric activity similar to the K-indices, but in more detail since the scalings are arithmetic and hourly in contrast to the 3-hourly quasi-logarithmic K-indices.

Telluric fluctuation activity. The fluctuation count is made on the same recorder as the N-S trace. The equipment consists of a 10-point stepping relay, a clutch driven microswitch, and an operations pen attached to the recorder. The switch is closed as the pen starts upscale and opens as it starts downscale. Thus within the sensitivity of the equipment the stepping relay advances one step for each cycle of fluctuations regardless of amplitude or pen position. At a recorder full scale range of 1000 mv/km the equipment will record fluctuations down to 5 mv/km. The data serve as an index of micropulsations activity showing diurnal, seasonal and sunspot cycle variations. The nighttime fluctuations are closely correlated with aurorally associated cosmic noise absorption. An indication of the micropulsation period in seconds can be obtained by dividing 3600 by the cycle per hour value.

The collection, analysis, and publication of these telluric current records and scalings is supported in part by the Air Force Cambridge Research Laboratories, Office of Aerospace Research under Contract No. AF 19(628)-1695, monitored by Mr. Elwood Maple.

FREQUENCY-TIME DISPLAYS OF TELLURIC CURRENT ACTIVITY

R. R. Heacock and V. P. Hessler

These frequency-time displays of electromagnetic micropulsation activity in the period range \sim 5.7 to 500 sec were recorded with the telluric current technique using the N-S College electrodes described in the preceding section. The telluric system has the advantage of larger low frequency response than an induction loop system and a better signal to noise ratio because of the millivolts available from the telluric electrodes in comparison with the microvolt signals of the induction loop. A magnetometer of the required dynamic and frequency range for this application would be far more expensive.

The amplifier is a Medistor microvoltmeter set at 10 mv range and logarithmic scale. The logarithmic response makes it possible to accomodate the wide dynamic range of activity which occurs at College in the frequency range under investigation. Thus with constant gain settings the low amplitude Pc 3 daytime activity can be brought out clearly on the sonograms, and with no overloading of the instrumentation due to the powerful nighttime Pi activity.

The tape recorder is a Knight 4000A AM recorder which has been modified to record at 1 1/6 inch per hour. The playback recorder is another Knight 4000A which has 15 ips tape speed. Thus a speedup factor of 46,000 is achieved. This speedup permits the display of 24 hours of data on one sonogram, and the resulting data period range is 5.7 to 500 secs.

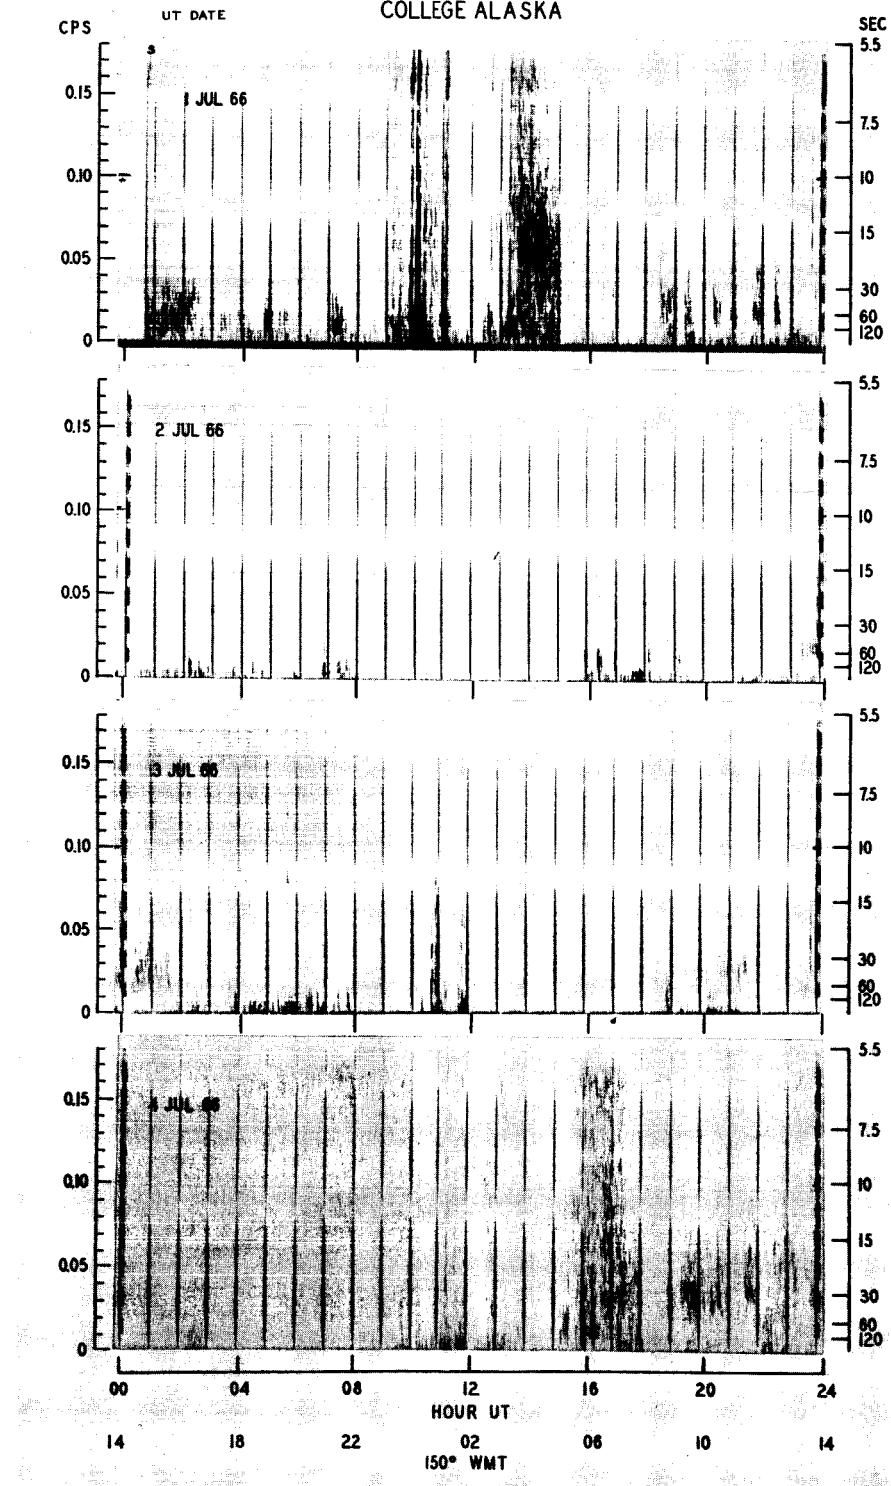

The playback amplifier is a Tektronix Type 122. The frequency response of the amplifier and Sonograph are shaped such that average activity at the bottom of sonograms is not too black and average activity at the top is not too faint. To accomplish this, the response was made to increase monotonically toward higher frequencies. If a flat response had been used, the upper part of the sonograms would usually be blank when a reasonable level was present at the bottom. The departure from flatness is not sufficient to significantly distort the Pc 3 - 5 activity; however, care should be used in interpreting near 0.1 cps, the actual frequency of maximum power will be somewhat lower, perhaps near 0.05 cps. One should thus not use these sonograms to infer the power spectra of the activity. The intent is to display the general frequency-time characteristics in all parts of the 5.7 - 500 sec period range.

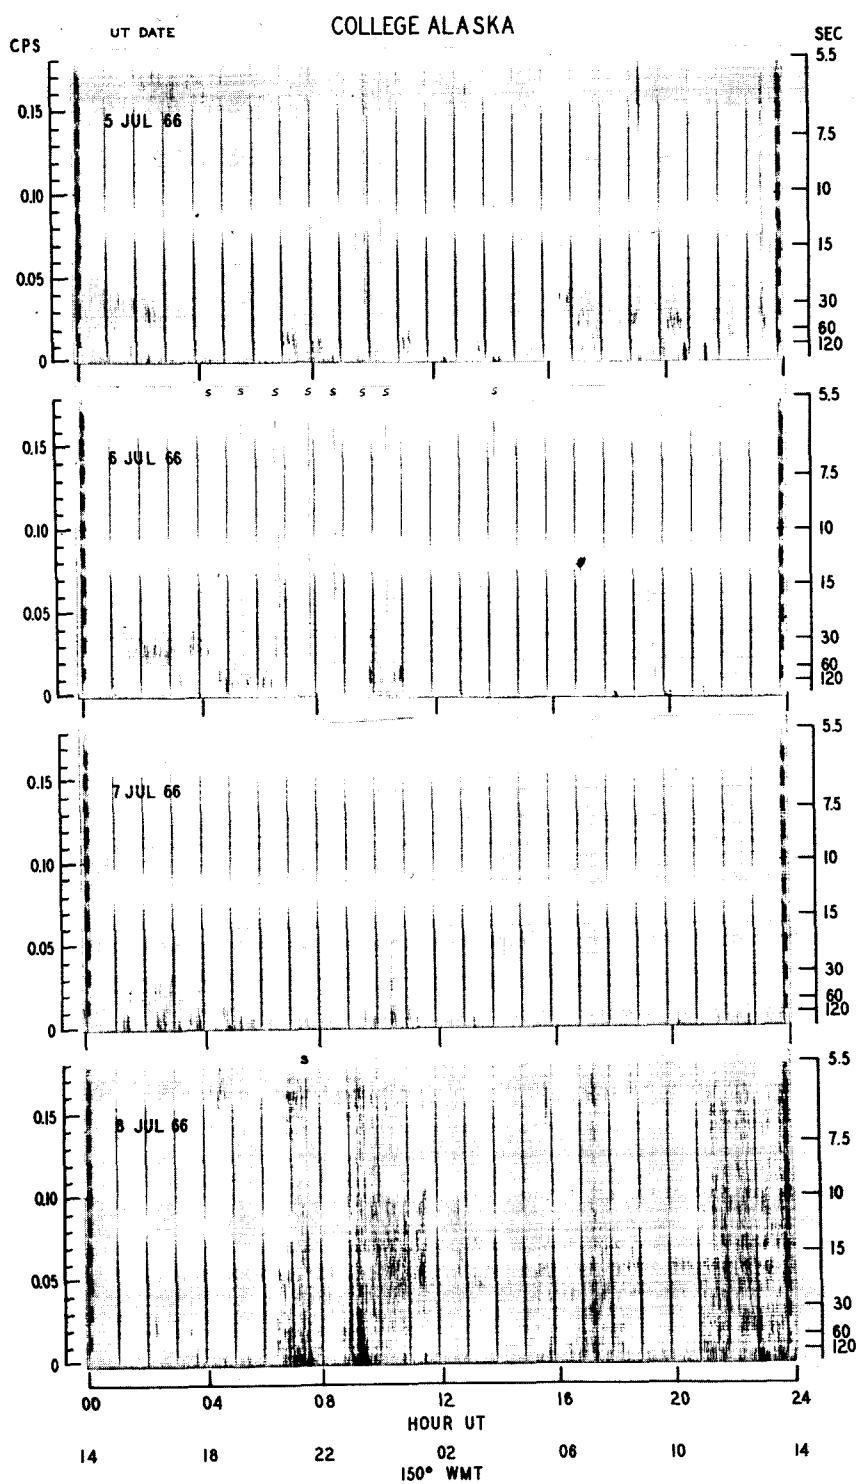

Spurious effects on the sonograms are indicated by an "S" at the top.

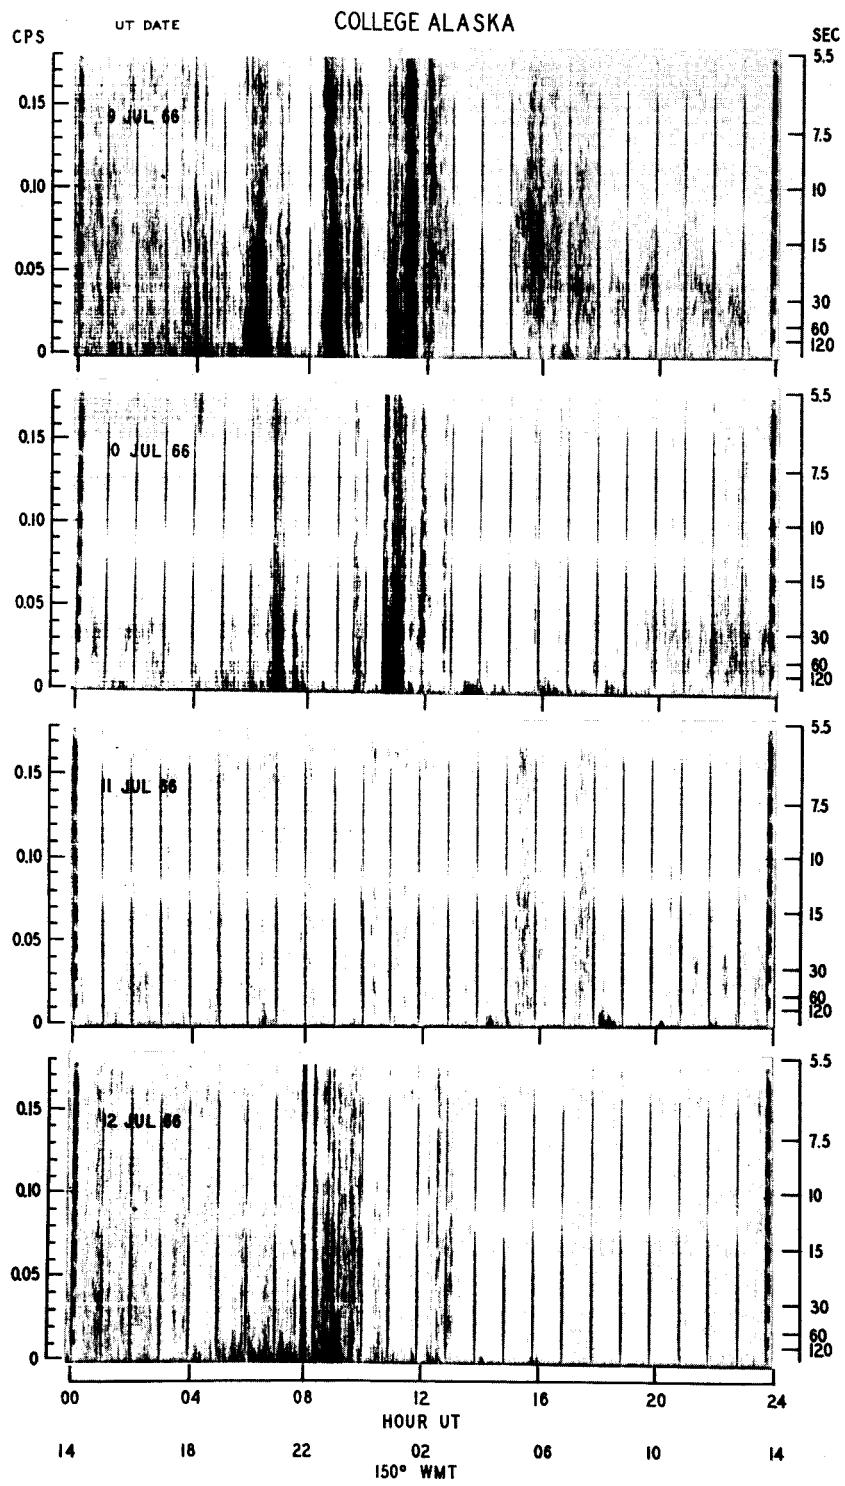

In general, these sonograms should be studied together with the telluric current time-amplitude traces given in the preceding section.

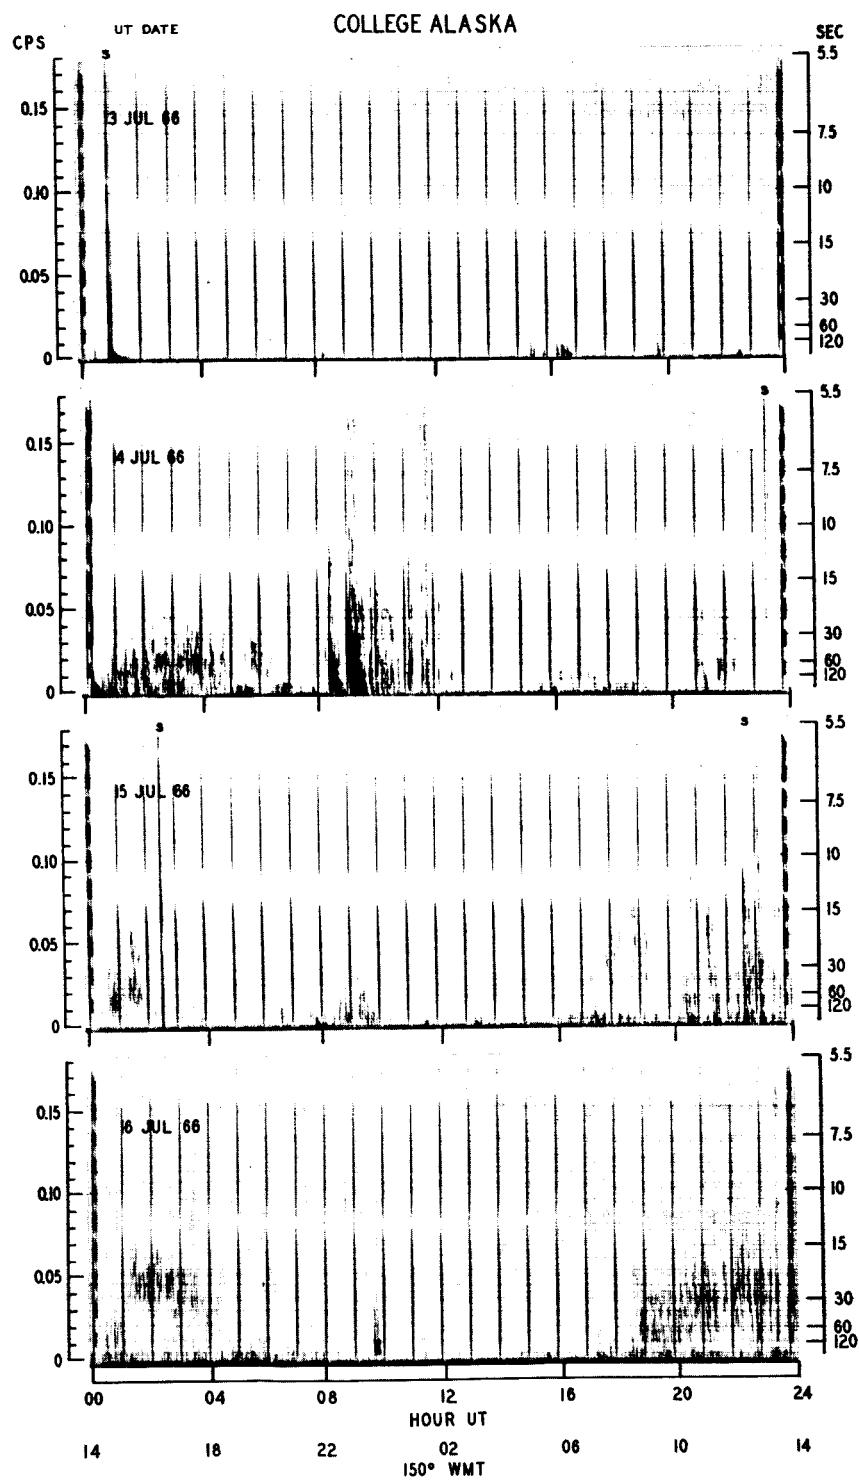

The collection and publication of these sonograms is supported jointly by the Office of Naval Research under Contract NONR 3010 (01) and by the Air Force Cambridge Research Laboratories, Office of Aerospace Research under Contract No. AF 19(628)-1695.

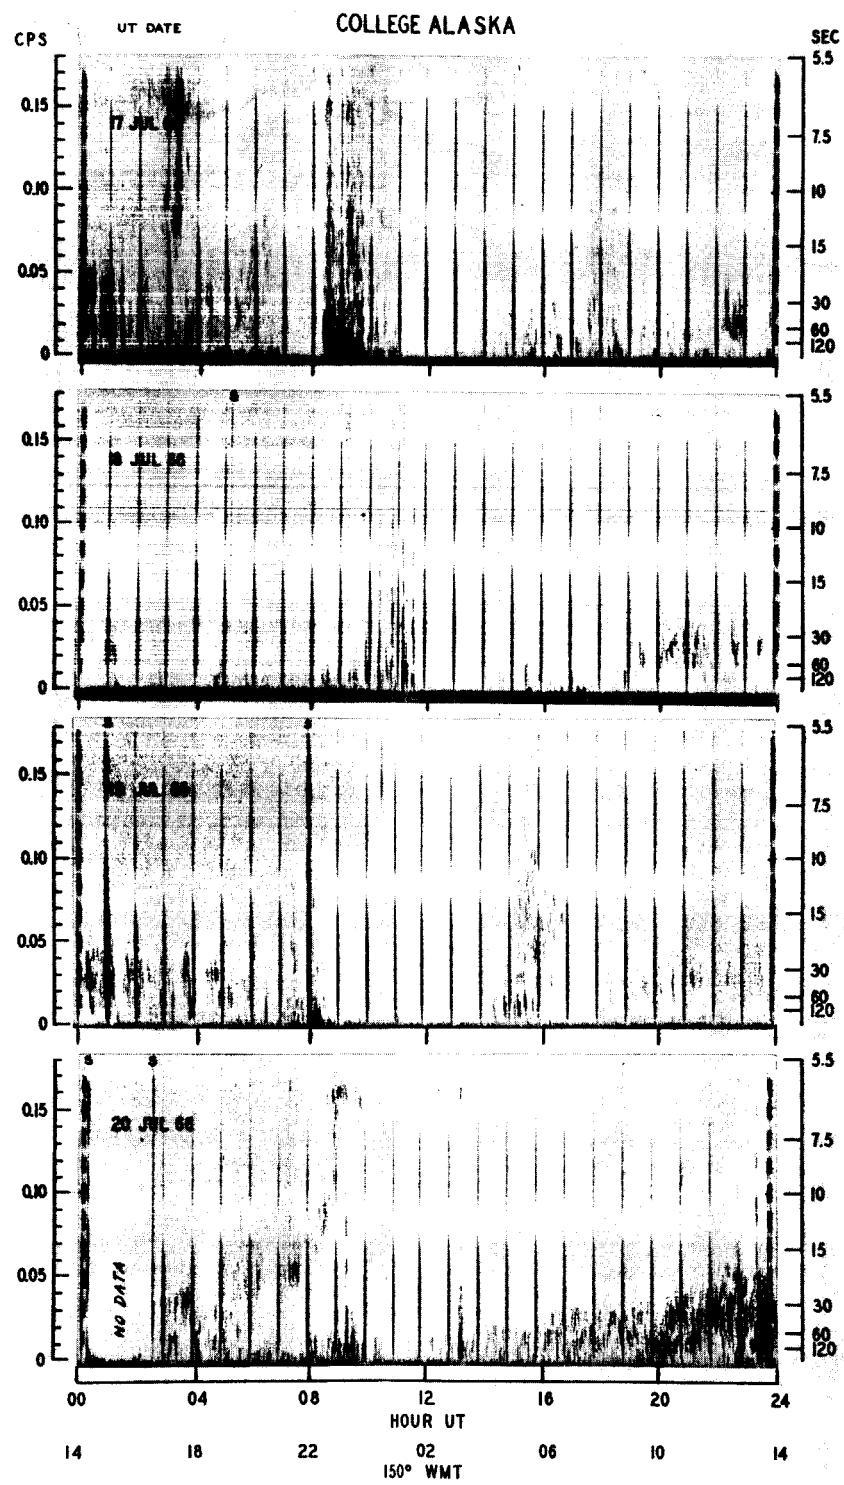

COLLEGE ALASKA

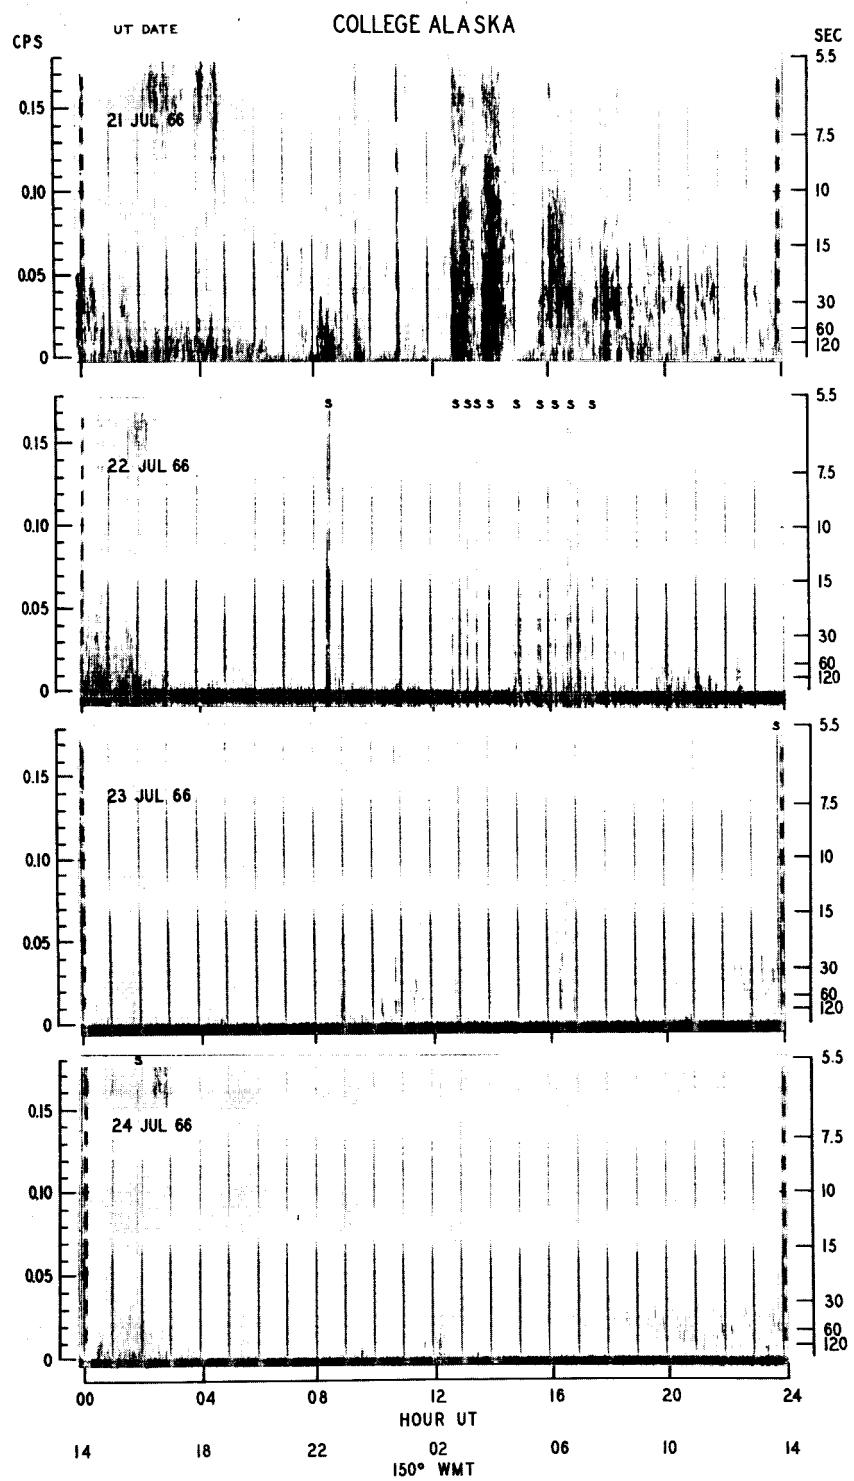

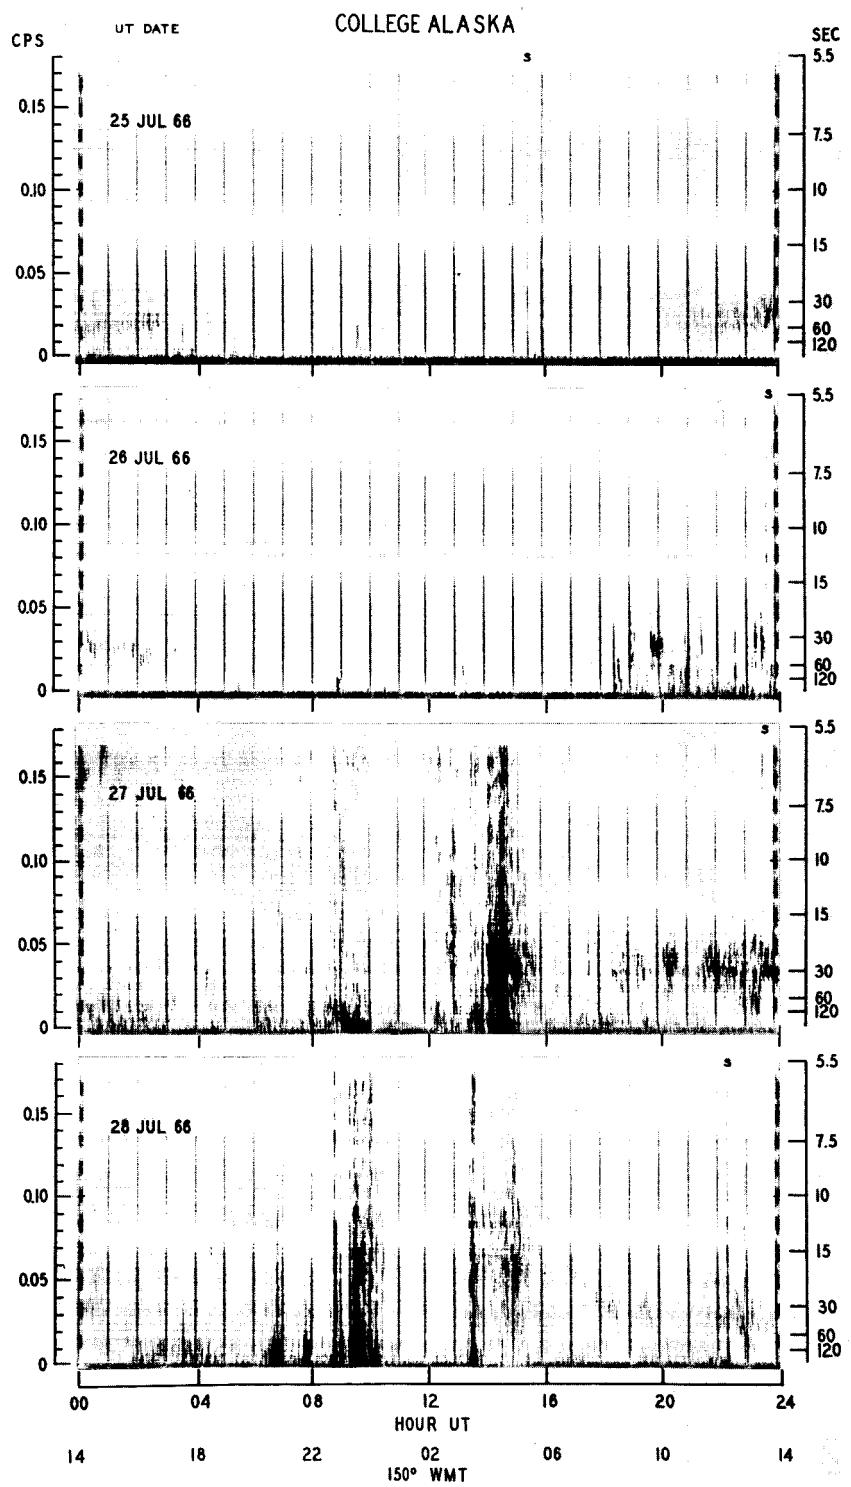

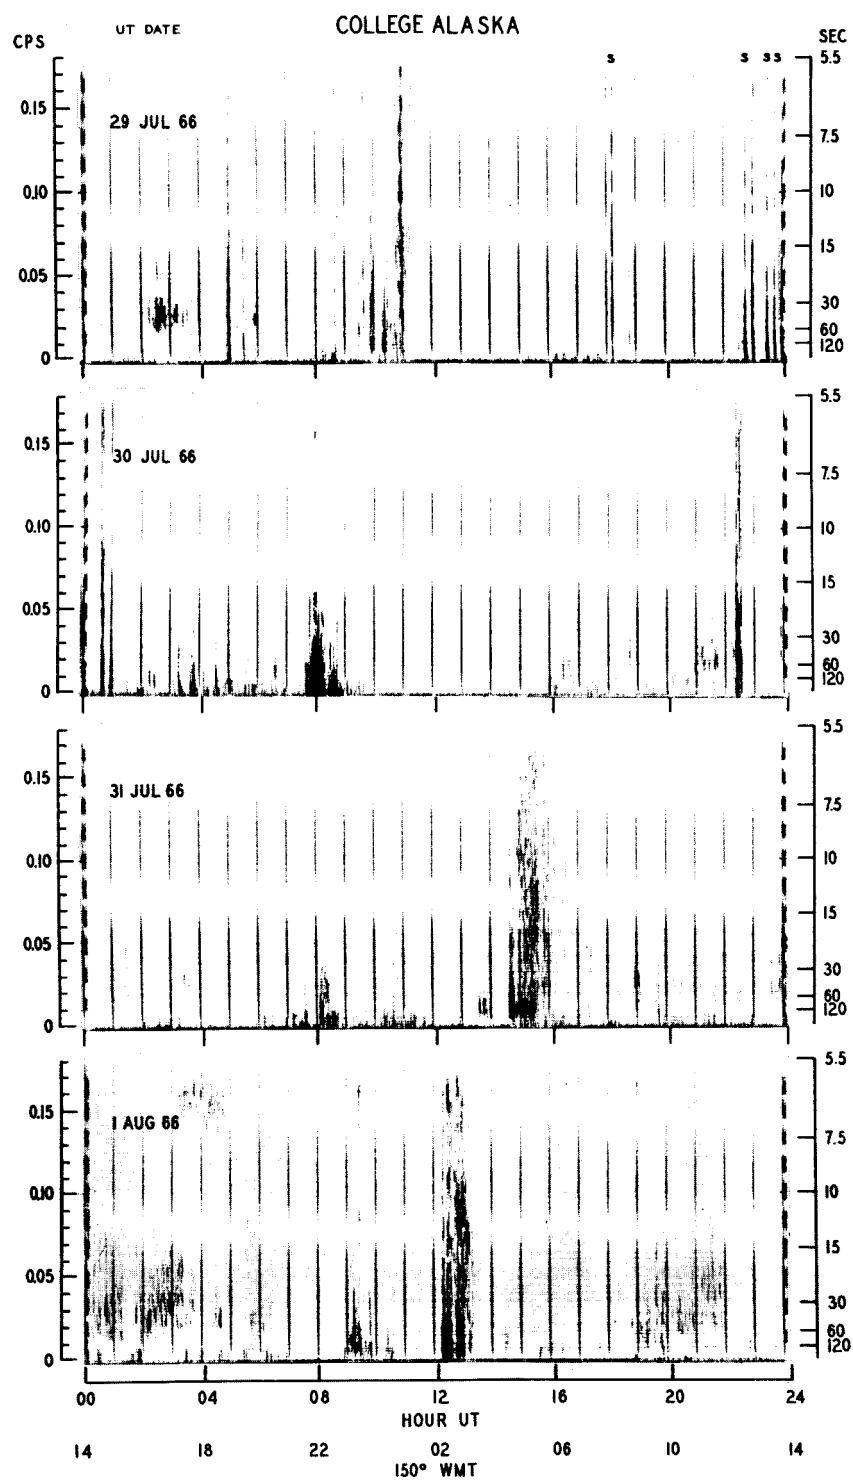

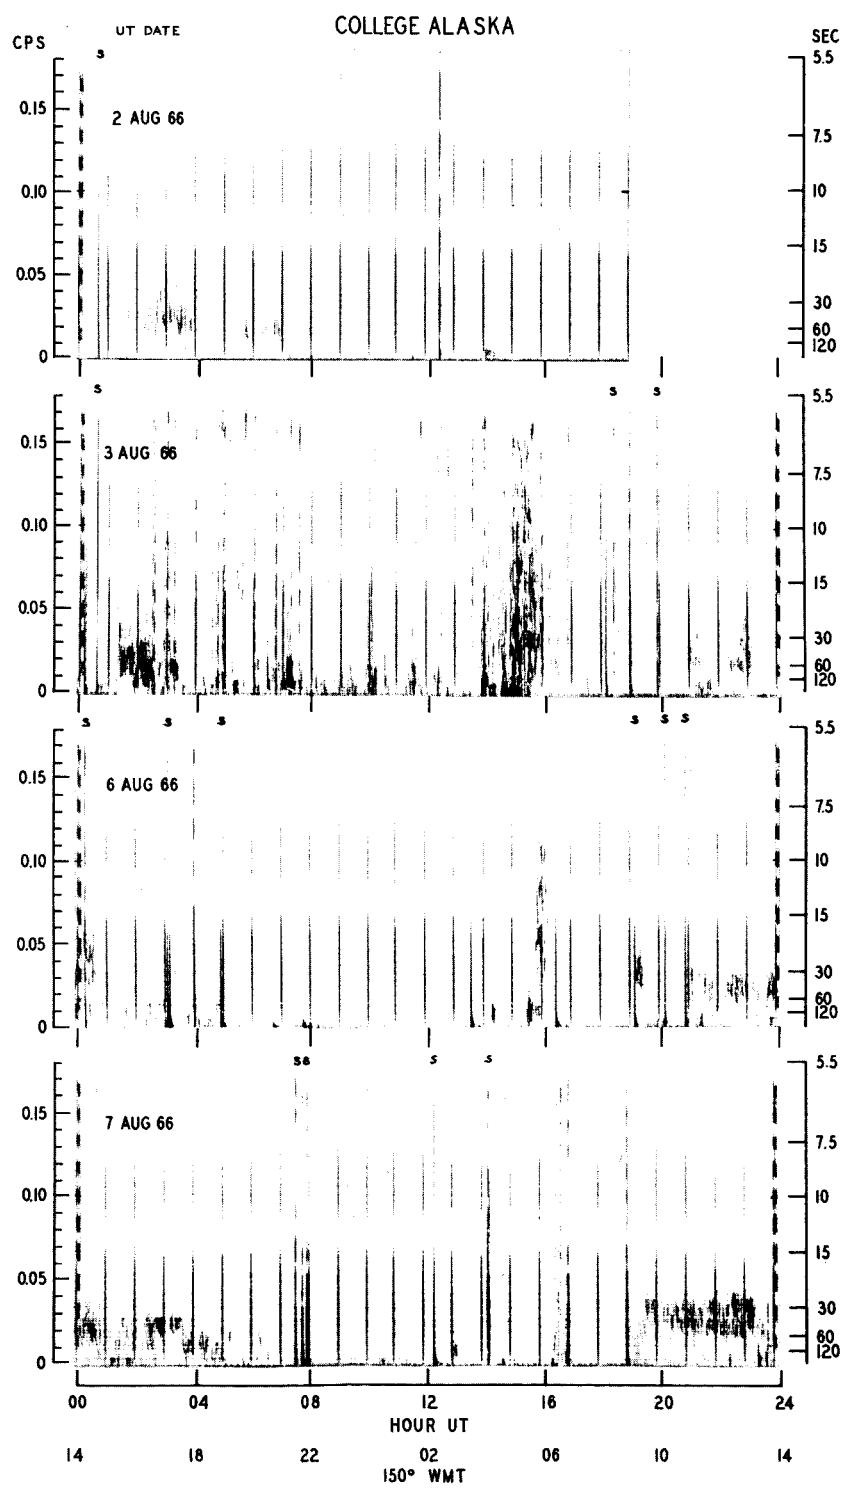

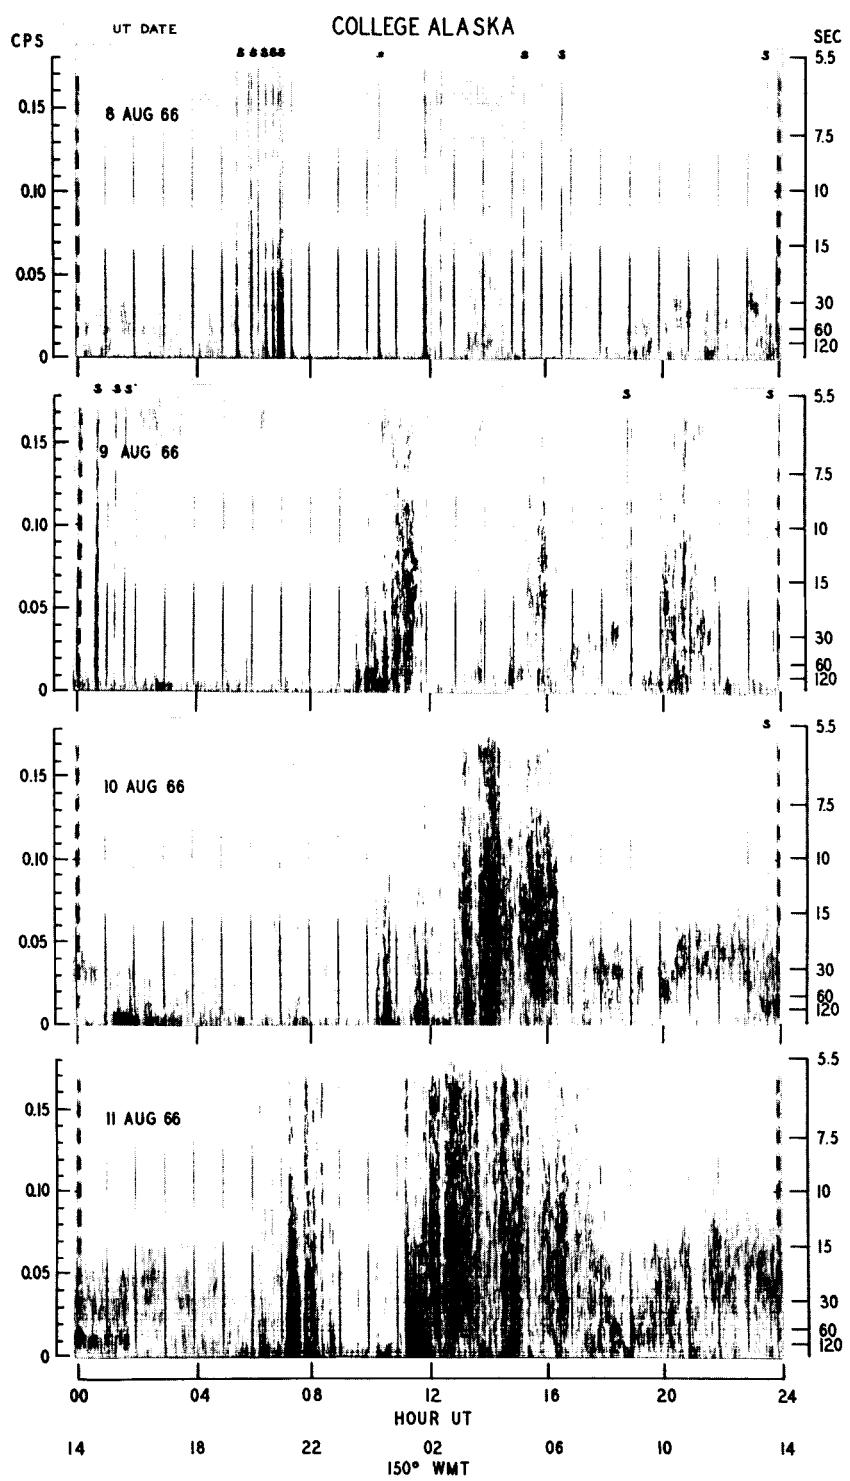

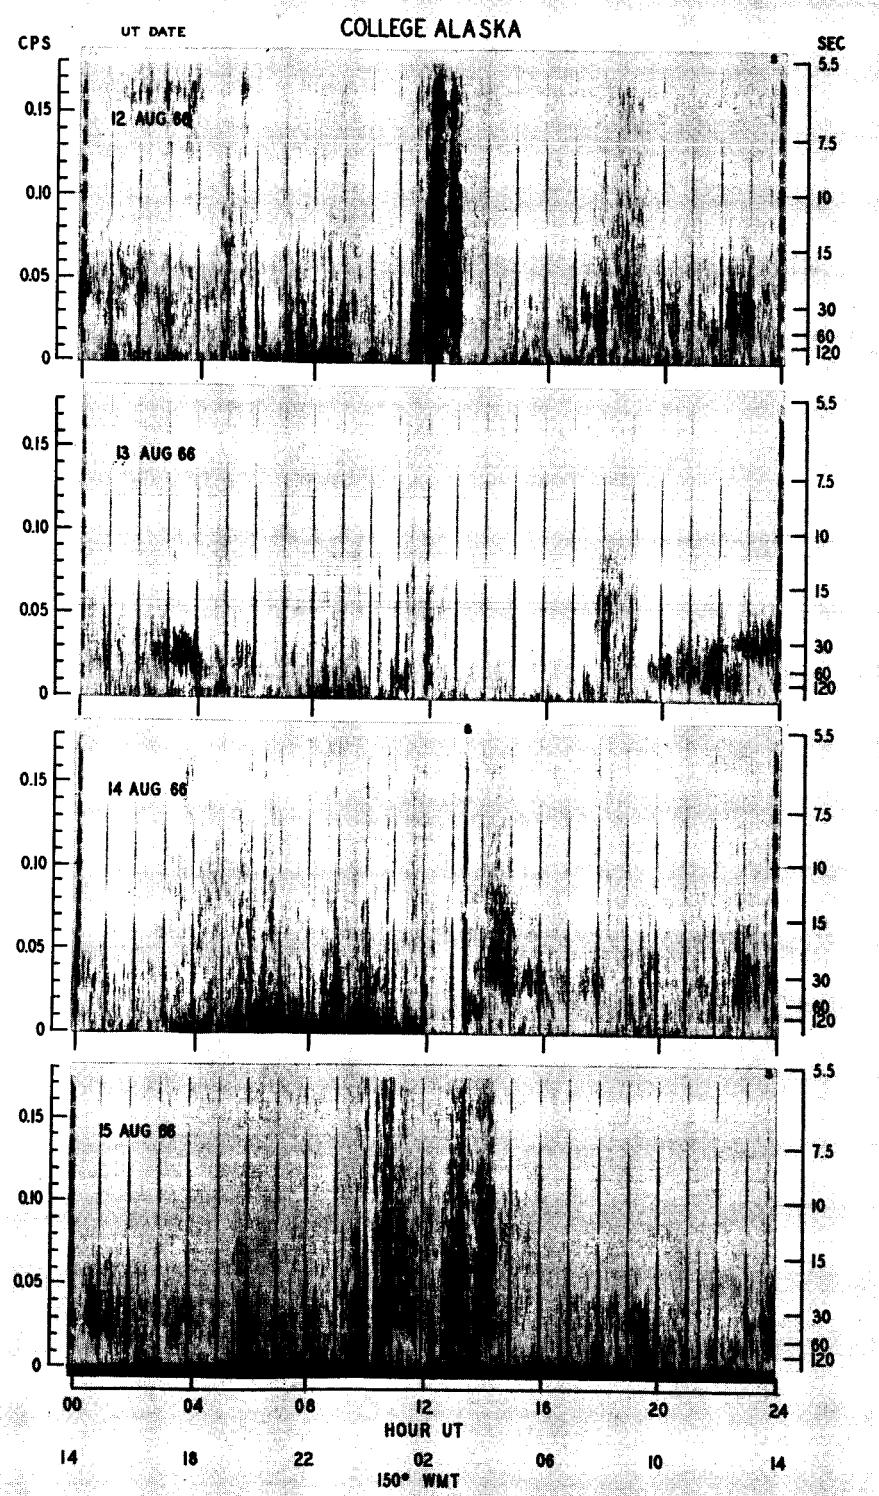

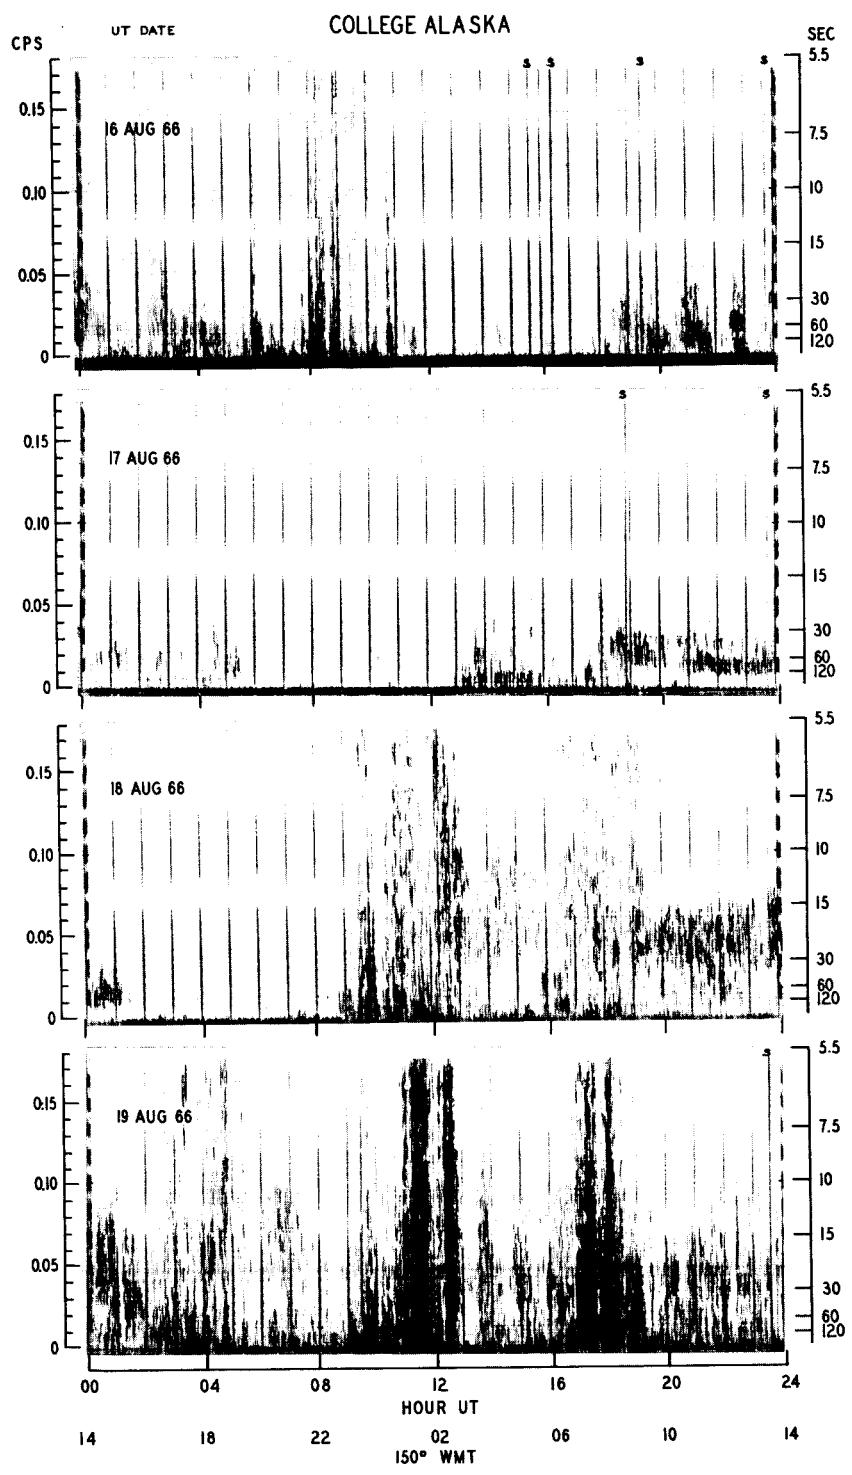

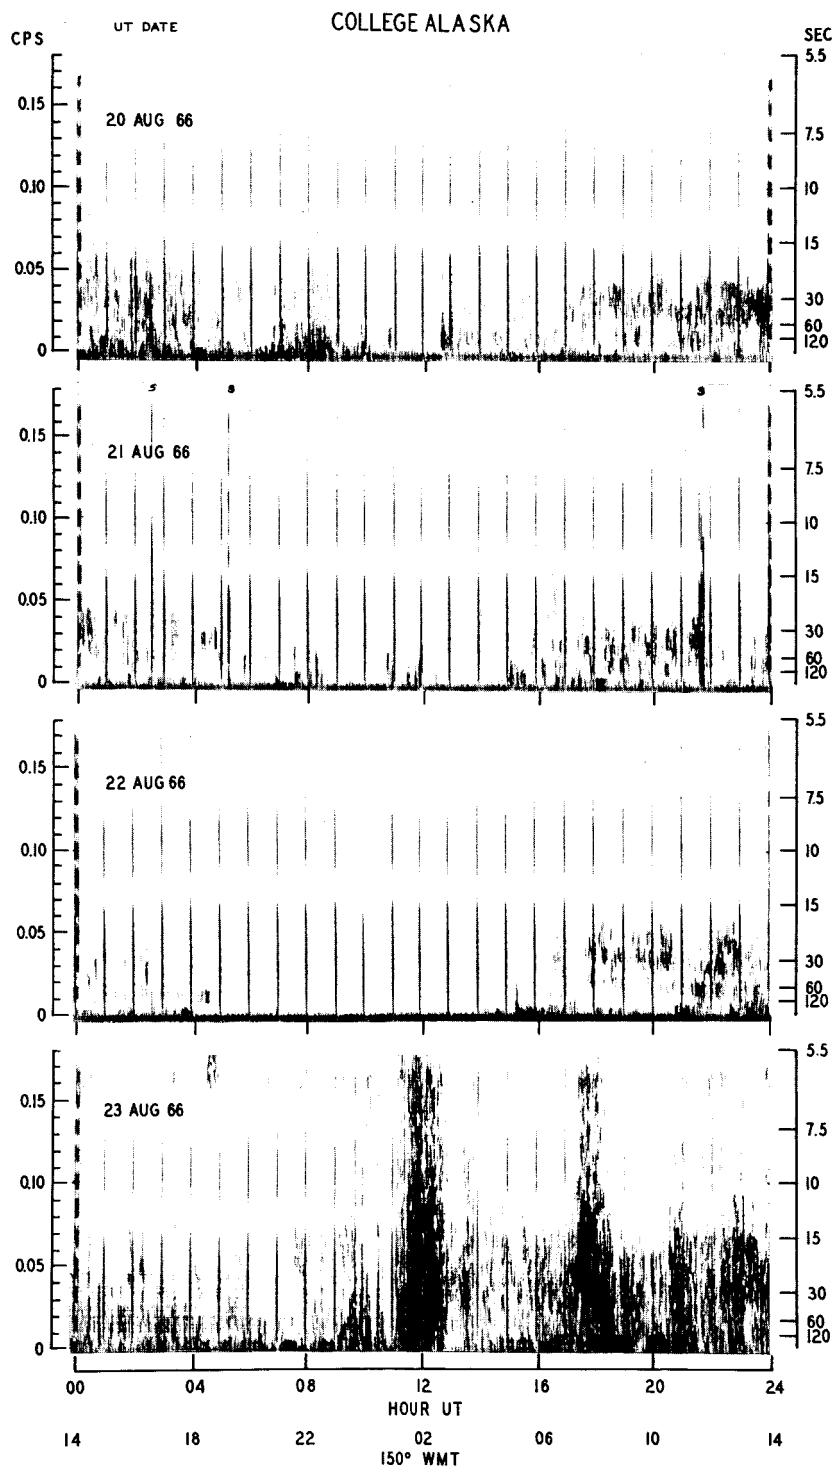

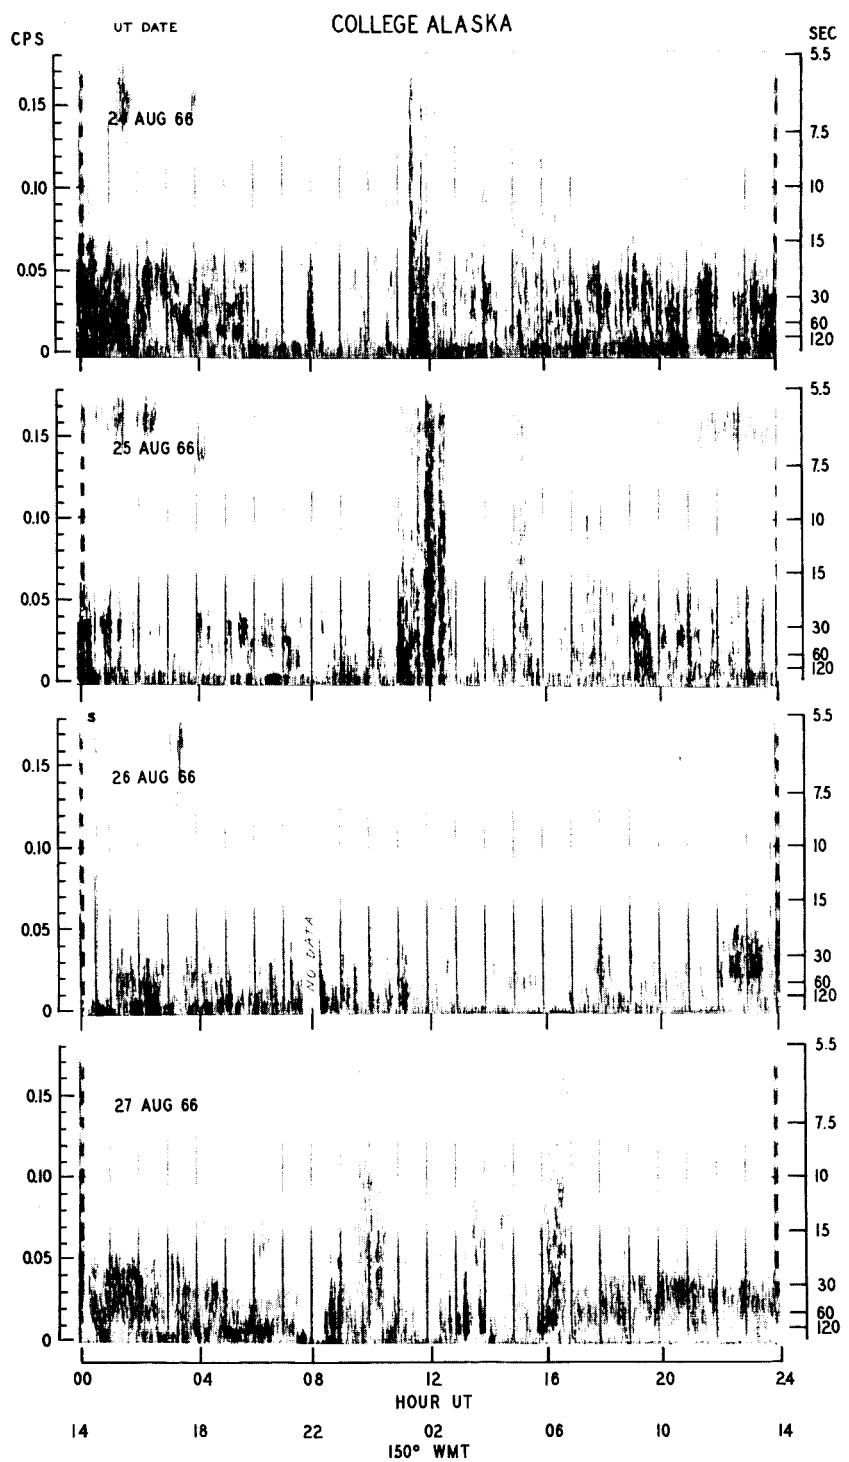

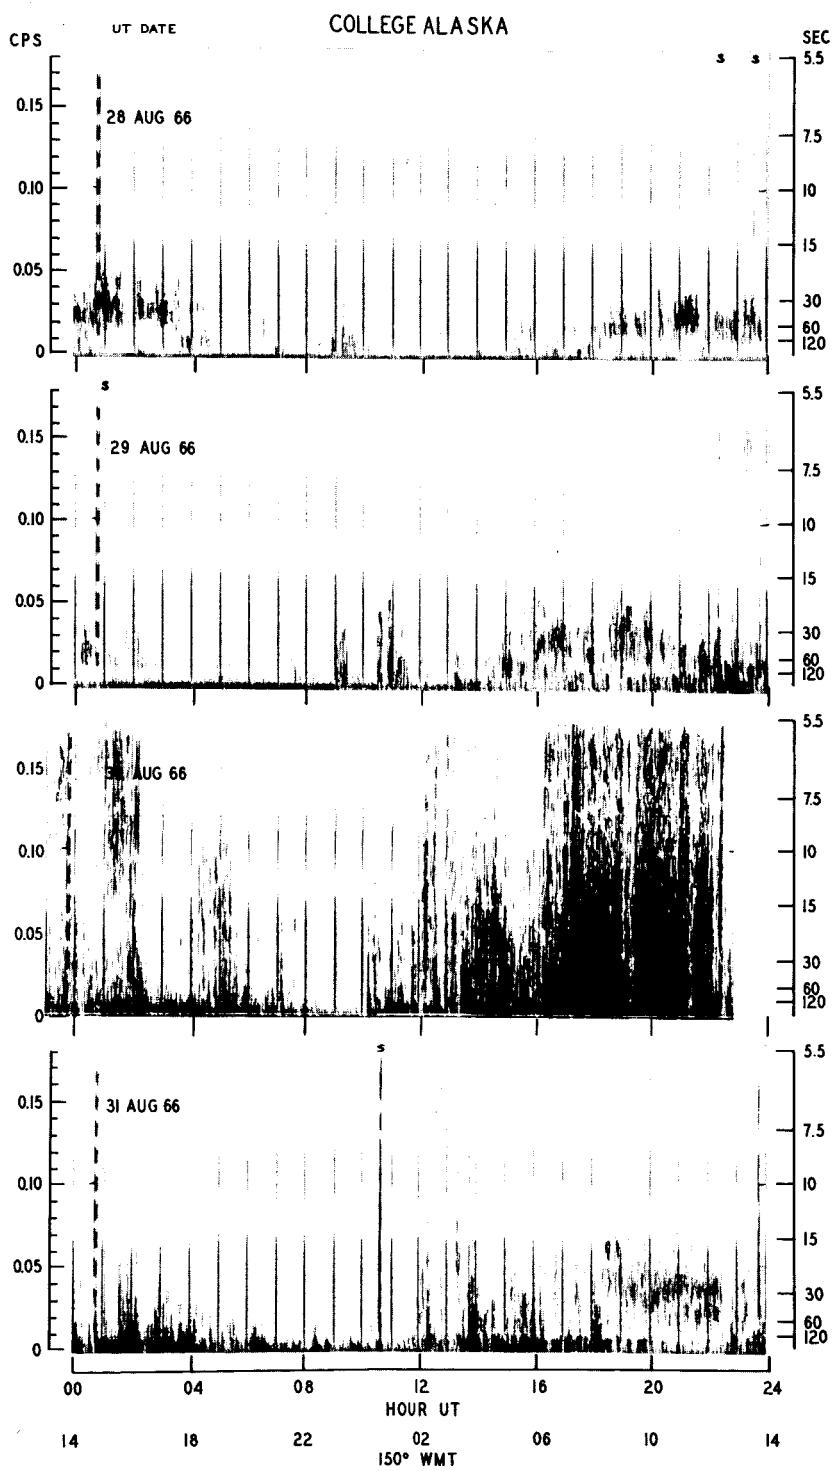

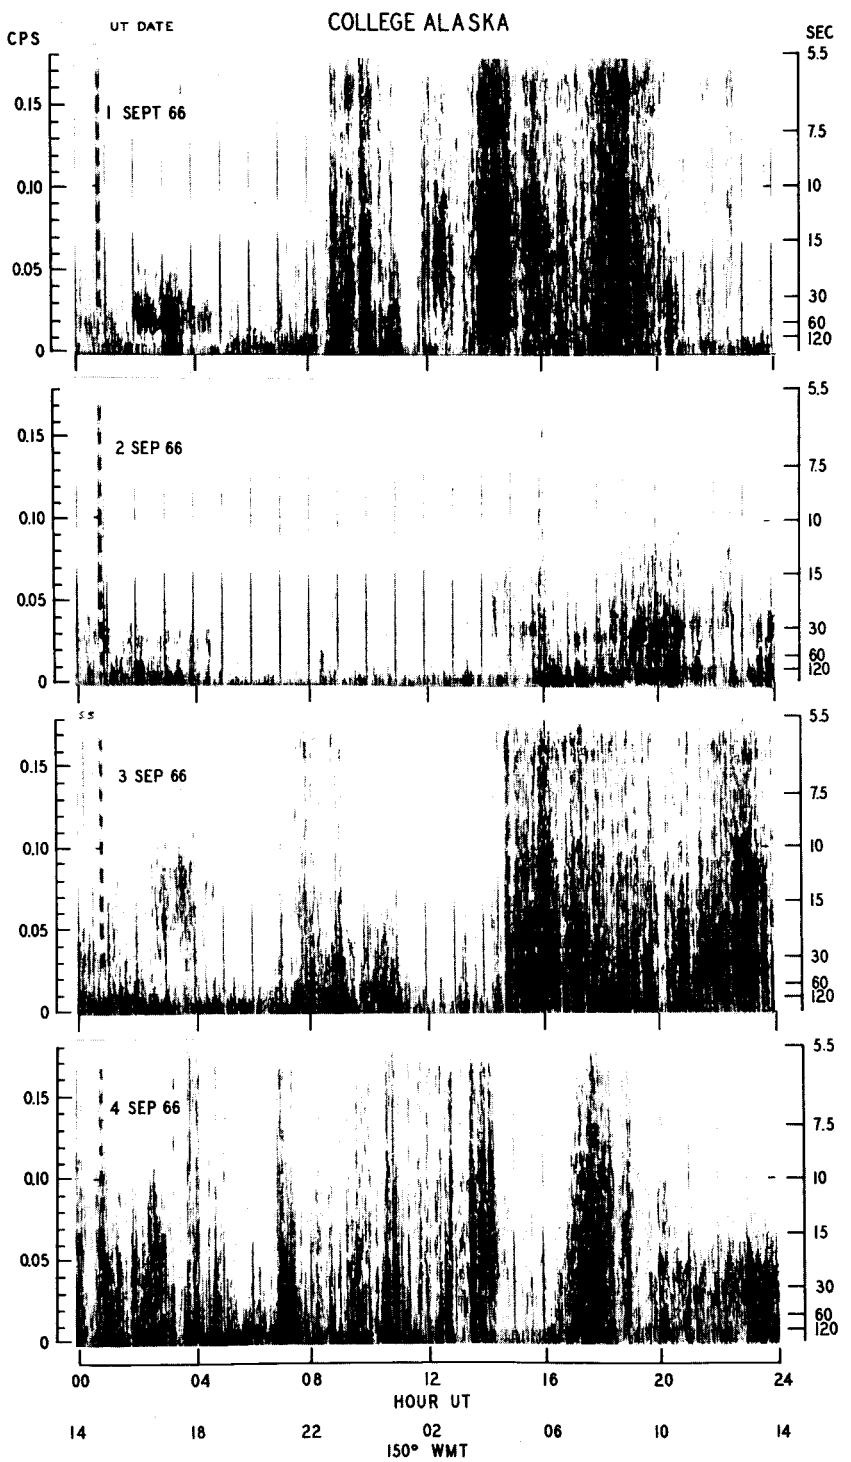

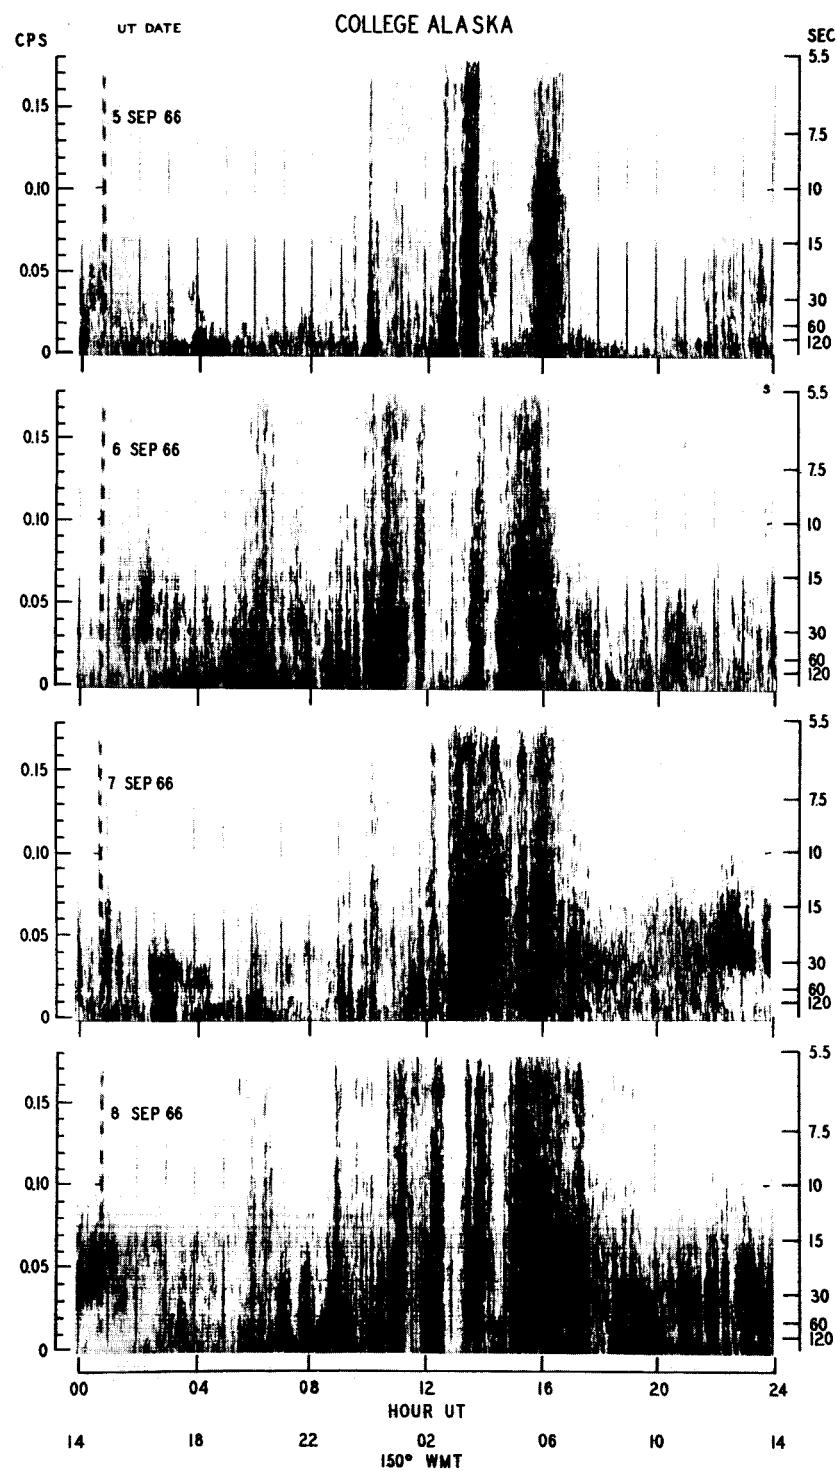

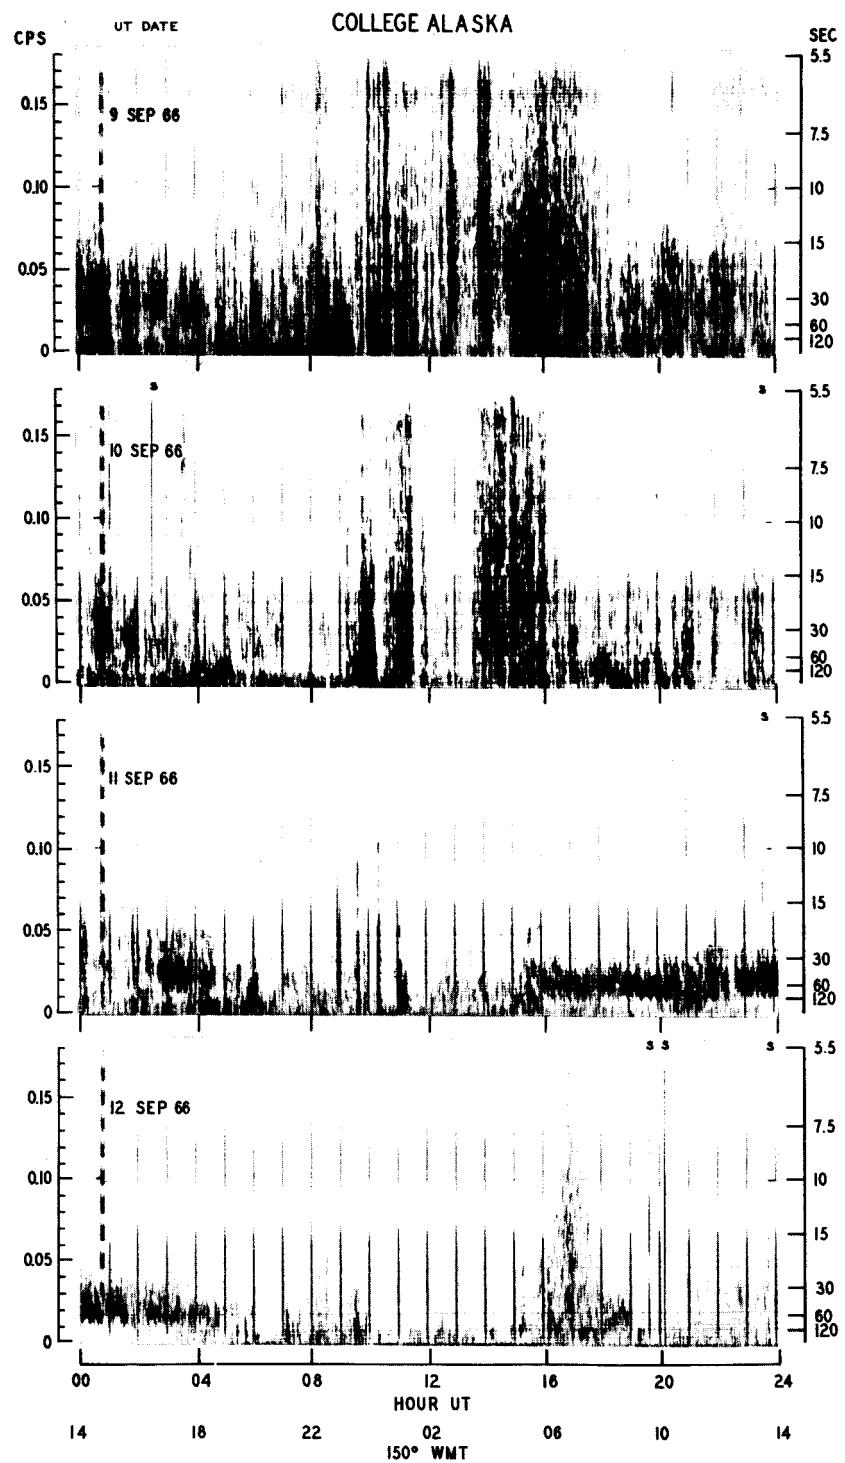

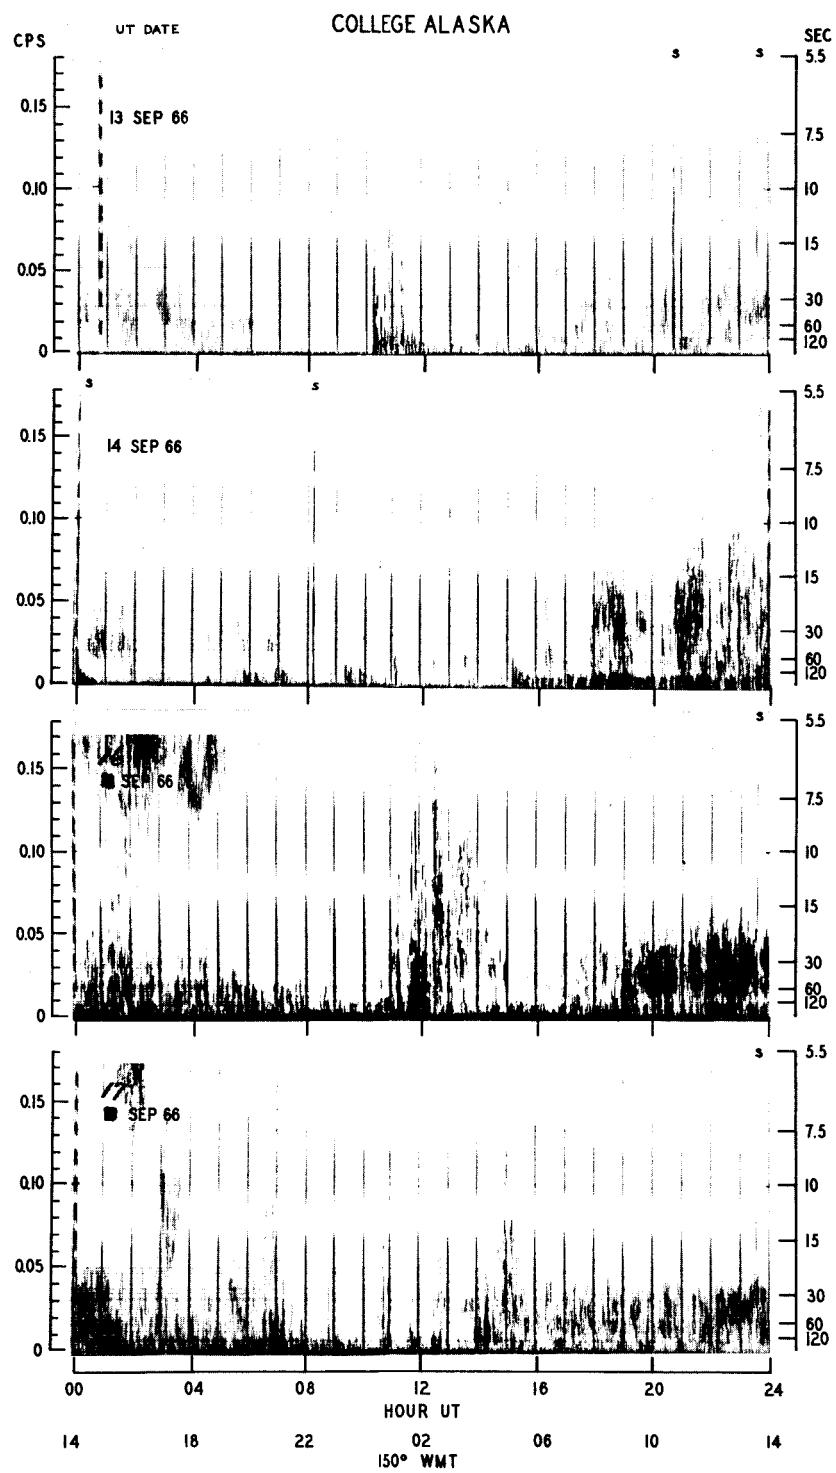

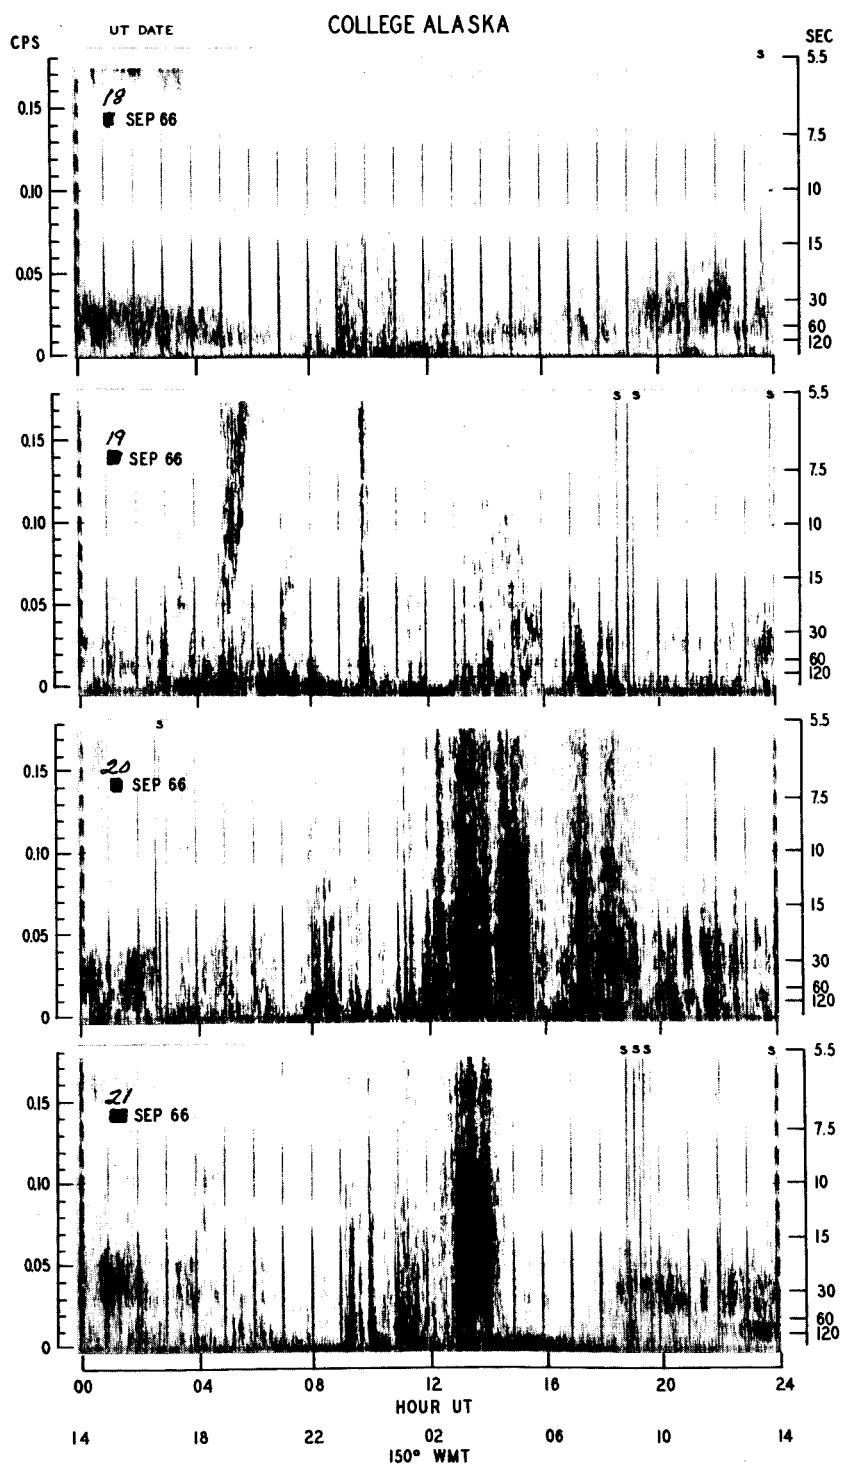

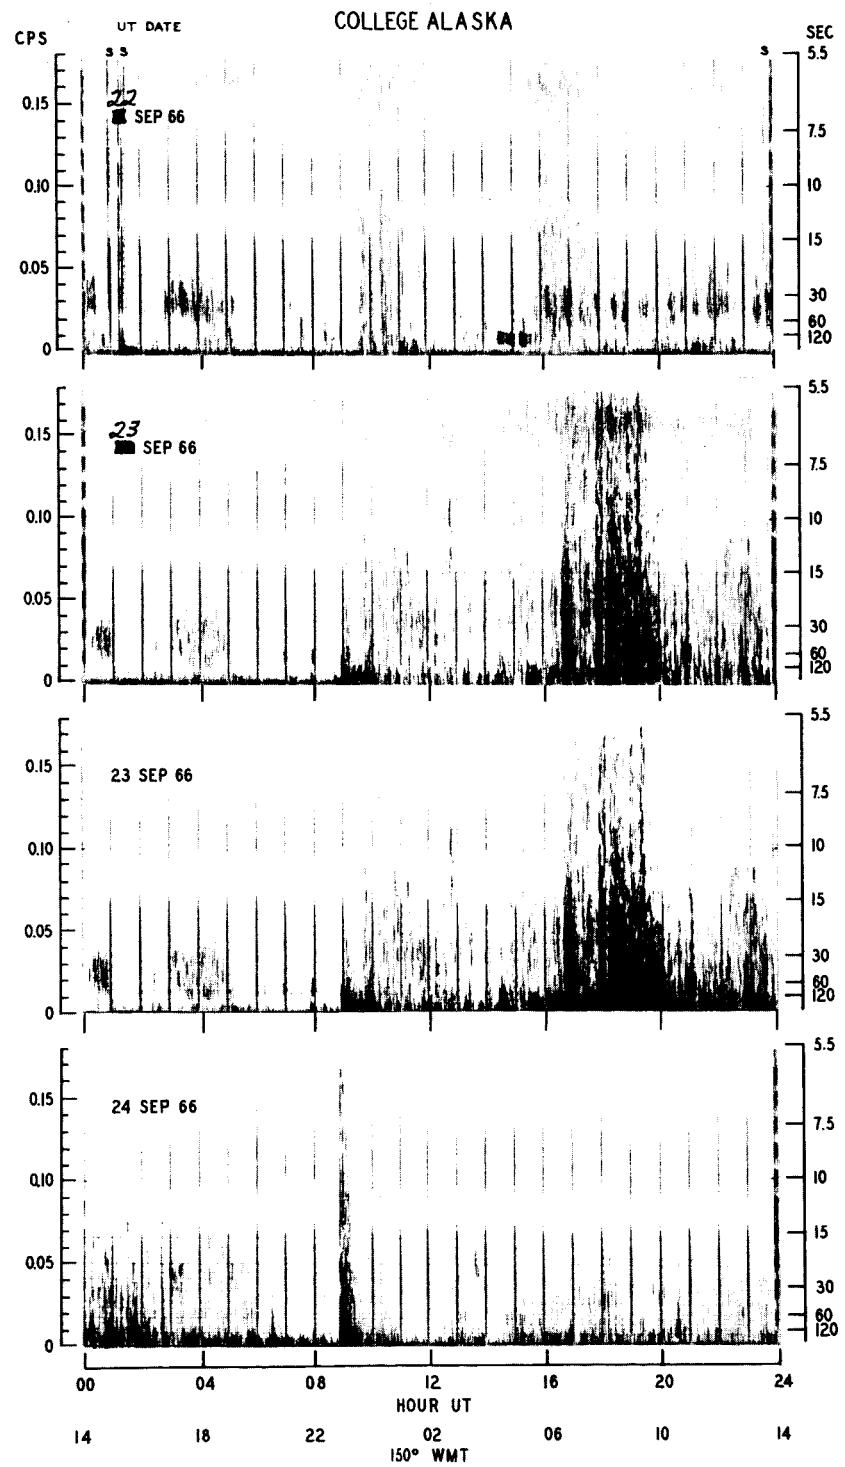

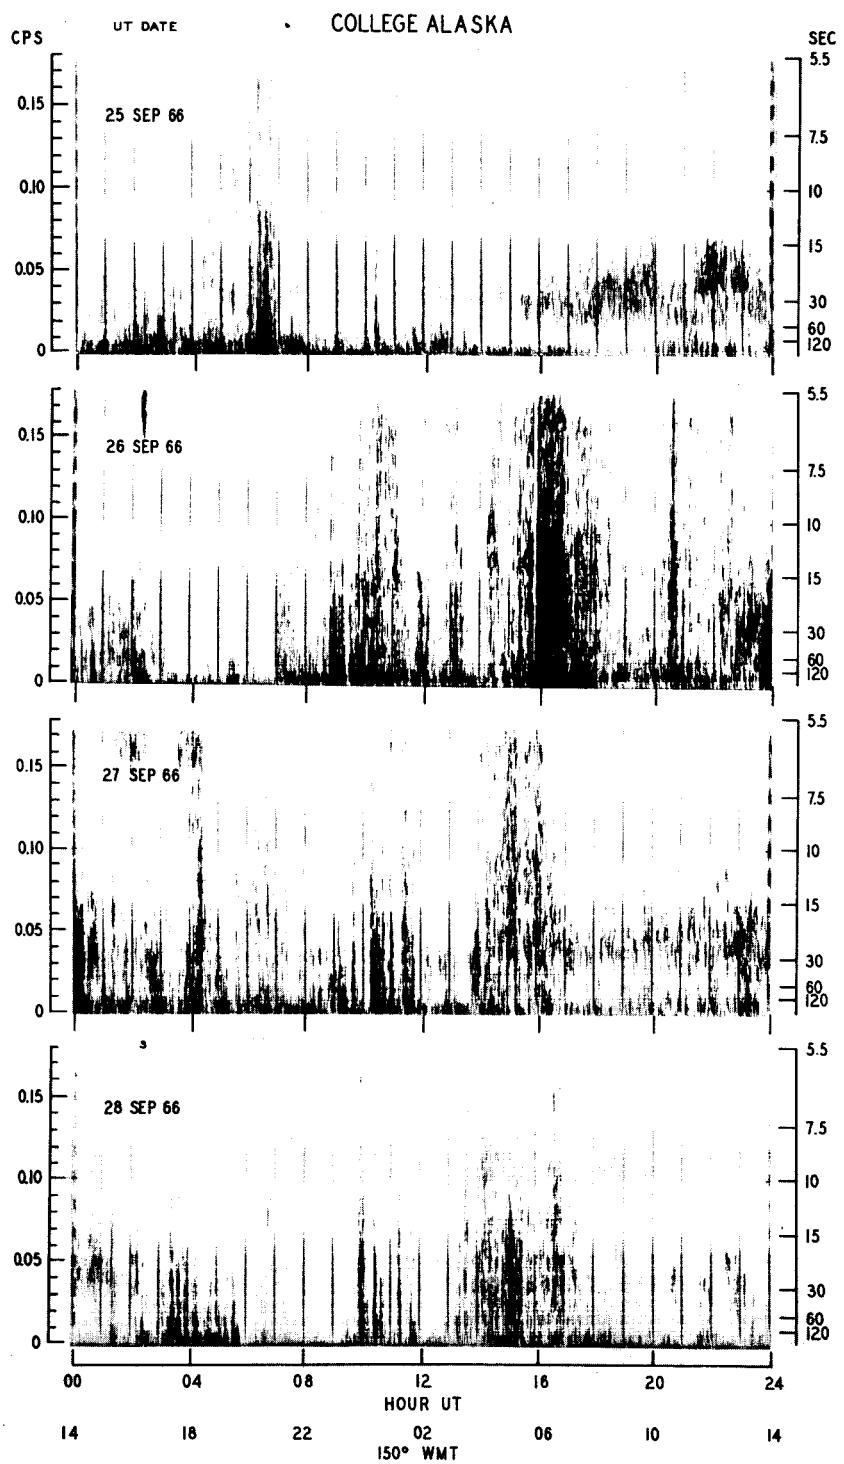

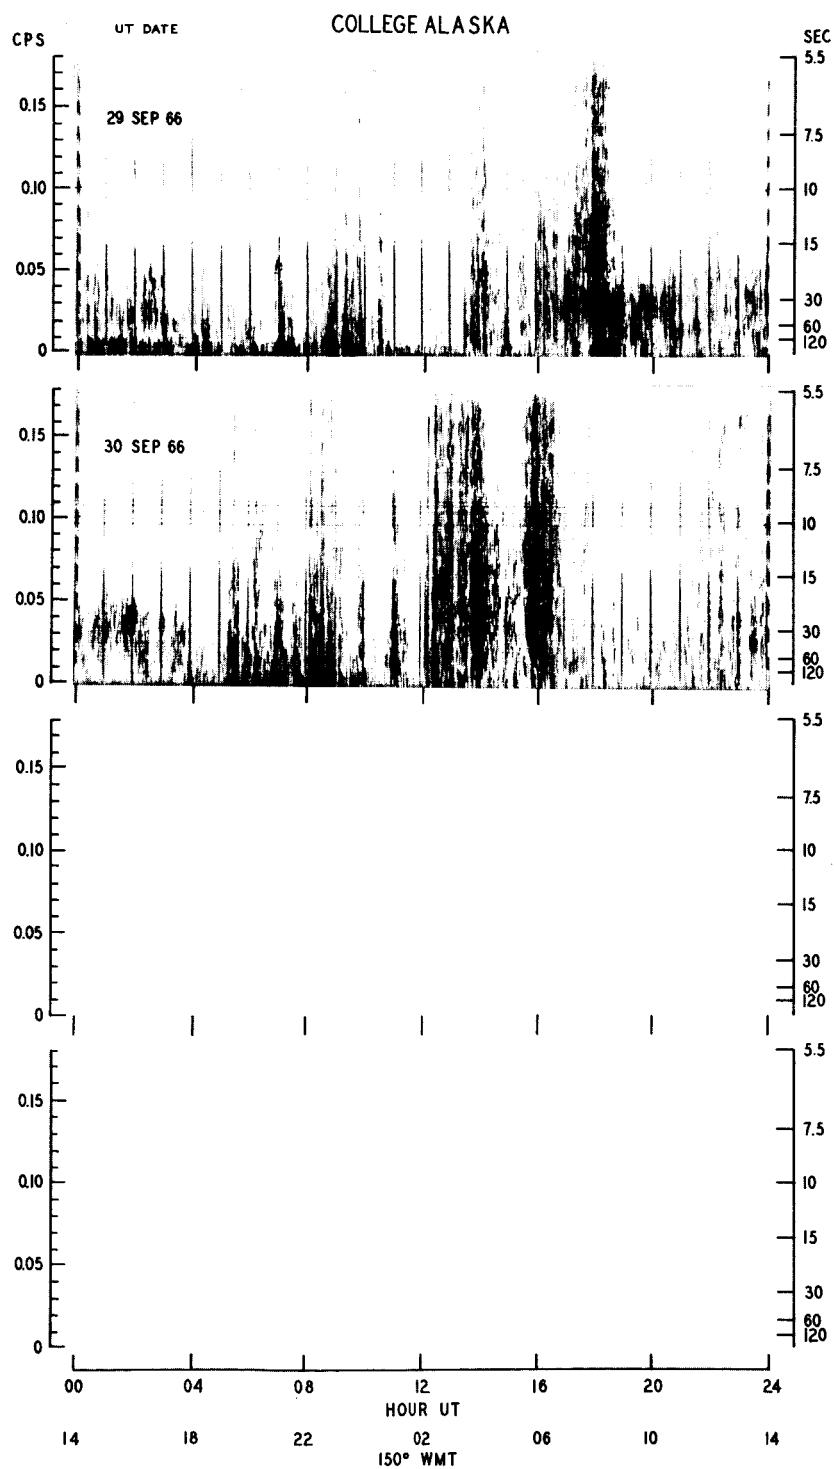

TELLURIC MICROPULSATION ACTIVITY - Pc 1

R. R. Heacock
Assistant Geophysicist

Instrumentation. The sensing elements are 200 meter spaced telluric current electrodes aligned north-south geographically. The recording system consists of a low pass LC 60 cps rejection filter, a 50k voltage divider gain control, a Tektronix type 122 preamplifier (X1000, h.f. cutoff 50 cps, l.f. cutoff 0.8 cps), a second 60 cps rejection filter, a Kronhite electronic band-pass filter with h.f. cutoff at 3 cps and l.f. cutoff at 0.06 cps, and an Esterline-Angus 1 ma recorder operating at a chart speed of 3/4" per min. Time mark signals furnished by the Institute operated NASA minitrack station are accurate to a millisecond.

The instrumentation has a rather flat response peak from 1 through 5 sec period essentially the period range of pearl-type micropulsations at College. Micropulsations are also being recorded continuously on tape, and the taped record has been inspected for evidence of pearl-type events at frequencies higher than 3 cps, with none being found to date.

Scaling procedures. The charts are inspected for half-hourly occurrences of pearl-type micropulsations. The criteria used for identification of pearls are a) a rather smooth "pearl"-like envelope, b) a rather constant pulse period in the range 0.5-10 secs, and c) a non-impulsive character (i.e. a small dynamic range). The maximum peak-to-peak amplitude of the pearl envelope is measured in each half-hour which contains more than ~ 1 minute of pearl-type activity, and this measurement is listed under amplitude, mv/km.

Sonograms (frequency-time displays) are made of the pearl events. The approximate upper and lower frequency bounds of the activity are scaled by half-hour intervals and are entered under Frequency.

The form of the pearl activity is determined from the sonogram. If the event contains periodic structures with period 1-8 minutes, an S is entered in the Form column. If the activity seems intermediate between Pc 1 and Pi 1, an I is entered under Form. Thus the activity indicated by "I" may have a broader and more diffuse frequency range than for typical Pc 1 activity, or the event may be more impulsive than for typical Pc 1. The occurrence rate of "I" events has some positive correlation with Kp values.

This micropulsation recording and analysis program is supported by the Air Force Cambridge Research Laboratories, Office of Aerospace Research, under Contract No. AF 19(628)-1695.

GEOMAGNETIC ACTIVITY, K, A_k , C

J. B. Townshend, Director

College Magnetic and Seismological Observatory
Environmental Science Services Administration

The K, A_k and C-indices for College are assigned at the Coast & Geodetic Survey's College Magnetic & Seismological Observatory located at the University of Alaska.

The K-index. The K-index is an indication of the intensity of the solar particle-radiation effects for each eight intervals beginning 00-03, 03-06...21 to 24 U.T. It is defined as, the difference between the highest and lowest deviation from a smooth curve to be expected for a component on a magnetically quiet day, within a three hour interval, according to the season, the sunspot cycle, and the phase of the moon. The K-indices are scaled from the Normal and Storm magnetograms, D and H traces and are based on the most disturbed component. The Z component is no longer used for determining K. The schedule for K-indices vs gamma range for College is as follows:

<u>Gamma Range</u>	<u>K-index</u>
0 < 25	0
25 < 50	1
50 < 100	2
100 < 200	3
200 < 350	4
350 < 600	5
600 < 1000	6
1000 < 1650	7
1650 < 2500	8
2500 +	9

The Equivalent Daily Amplitude, A_k . The K-index is converted into an equivalent range, a_k which is near the center of the limiting gamma ranges for a given grade of K. The average of the eight values a_k is called the equivalent daily amplitude A_k . For College the equivalent a_k for K is:

$$\begin{array}{cccccccccc} K = 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 \\ a_k = 0 & 3 & 7 & 15 & 27 & 48 & 80 & 140 & 240 & 400 \end{array} (10^Y)$$

The unit 10^Y has been chosen so as not to give the illusion of an accuracy not justified. The table for the re-conversion of K into an equivalent amplitude a_k is conventional and differs somewhat from the values adopted for the center of the limiting gamma range. The difference is of importance only in special studies, therefore, the conventional re-conversion of K into a_k is used.

The Magnetic Daily Character-Figure C. To each Universal day a character is assigned on the basis C=0, if it is quiet; C=1; if it is normal or moderately disturbed; C=2, if it is greatly disturbed. The method used to assign characters at the College Observatory is based on A_k as follows:

<u>A_k range</u>	<u>C</u>
0 < 11	0
11 < 50	1
50 +	2

E R R A T A

Note that daily sonograms for 4 August, 5 August, and 15 September are missing.

A group of the September sonograms were dated incorrectly.

The dates on all sonograms dated from 15 September, 1966 through 22 September 1966 should be changed to one day later. Note that this will result in two sonograms dated 23 September 1966, which are actually observed to be identical.

All sonograms published since 1 January 1966 have now been rechecked for dates. All are correct.

V.P.H.
